# **Chemistry 247B Hanson**

#### Sample Exam 4B

In each case, read each possible answer, use a process of elimination, and circle the BEST answer. If you are having trouble deciding between two answers, briefly explain your final choice. If you do so, use just a few words, just to clue me in to what you are thinking. Do not dwell on any particular problem for an extended period of time. Each is worth 2 points.

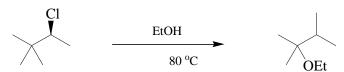

- 1. In the reaction shown above the nucleophile is
  - (a) Na
- (b) NaC≡CH
- (c) HC≡C<sup>-</sup>
- (d) HC≡CH

$$Cl$$
 $Na_2CO_3$ 
 $H_2O$ 
 $OH$ 

- 2. In the reaction shown above the nucleophile is
  - (a) Na<sub>2</sub>CO<sub>3</sub>
- (b) H<sub>2</sub>O
- (c)  $OH^-$
- (d)  $CO_3^{2-}$

- 3. In the reaction shown above the function of Na<sub>2</sub>CO<sub>3</sub> is
  - (a) to produce the OH<sup>-</sup> needed for the reaction
  - (b) to absorb the Cl<sup>-</sup> produced in the reaction
  - (c) to act as a strong base
  - (d) to act as the nucleophile

- 4. The reaction shown above works because
  - (a) sodium iodide is insoluble in acetone
  - (b) sodium bromide is insoluble in acetone
  - (c) S<sub>N</sub>1 reactions work particularly well in nonpolar solvents
  - (d) bromide is a better leaving group than iodide

5. In the above reaction the nucleophile is

- (a) Cl<sup>-</sup>
- (b) CH<sub>3</sub>CH<sub>2</sub>OH
- (c) CH<sub>3</sub>CH<sub>2</sub>O
- (d)  $H_2O$

6. The mechanism of the above reaction is

- (a)  $S_N 1$
- (b)  $S_N 2$
- (c) E1

(d) E2

7. In the mechanism for the above reaction:

- (a) There are two intermediates and three transition states
- (b) There are three intermediates and three transition states
- (c) There are three intermediates and four transition states
- (d) There are four intermediates and four transition states

8. Comparing the two reactions above, we see that

- (a) E2 eliminations can occur even without a strong base
- (b) the equatorial chloride gives the better stereoselectivity in the elimination reaction
- (c) in E1 reactions, the cation and anion are not always fully separated
- (d) the direction of an E2 elimination in a cyclic system depends upon the stereochemistry

- 9. The main difference between these two reactions is that:
  - (a) In the first case, the Cl is axial, and in the second it is equatorial.
  - (b) In the first case, the Cl is equatorial, and in the second case it is axial.
- 10. The reaction that would be expected to go faster would be:
  - (a) The first case, because an equatorial chloride is more stable.
  - (b) The second case, because an equatorial chloride is more stable.
  - (c) The first case, because the axial chloride can undergo anti E2 elimination.
  - (d) The second case, because the axial chloride can undergo anti E2 elimination.
- 11. The reason the second reaction is so selective in terms of the alkenes produced is that:
  - (a) anti E2 elimination can only go that way.
  - (b) syni E2 elimination can only go that way.
  - (c) There is less chance of substitution in that case.
  - (d) E2 elimination is impossible, so E1 elimination occurs instead.

(d) E2

- 12. The mechanism of the above reaction is
  - (a)  $S_N 1$  (b)  $S_N 2$  (c) E1
- 13. The reason this elimination goes the direction it does is that:
  - (a) That is the only way you can get anti elimination.
  - (b) The reaction follows Zaitsev's rule.
  - (c) The other direction would have to go through the cation.
  - (d) Elimination the other way would give an impossibly strained alkene.

- 14. The major product in this case is the *trans* alkene because:
  - (a) That is what Zaitsev's rule demands.
  - (b) The nucleophile is quite bulky.
  - (c) The reaction goes through an E2, not an E1, mechanism.
  - (d) The stability of the alkene is reflected in the transition state.
- 15. If the base used in this reaction were KO-*t*-Bu in HO-*t*-Bu, then:
  - (a) We would expect more elimination.
  - (b) The major product would be *cis*-2-pentene.
  - (c) The major product would still be trans-2-pentene.
  - (d) There would be less 1-pentene.

### 16. The primary lesson here is that:

- (a) even with a bulky base a primary alkyl halide can give a substantial amount of substitution
- (b) primary bromides primarily give substitution, even with a strong base
- (c) using a protic solvent is a bad idea if what you are looking for is elimination
- (d) there is no lesson here

#### 17. The mechanism here is

(a)  $S_N 1$ 

(b)  $S_N 2$ 

(c) E1

(d) E2

# 18. The primary lesson here is that:

- (a) Tertiary bromides undergo E2 reactions.
- (b) Use a bulky base to reduce the amount of substitution.
- (c) A bulky base can result in a "violation" of Zaitsev's rule.
- (d) Disubstituted alkenes are more stable than trisubstituted alkenes.

# 19. If NaOH in water were used instead for the base in this case we would expect:

- (a) more substitution.
- (b) more 2-methyl-2-butene.
- (c) more 2-methyl-1-butene.

### 20. DBU is used in this reaction

- (a) because it is a strong base.
- (b) because it is a good nucleophile.
- (c) because it is a weak base.

Br 
$$20\% \text{ H}_2\text{O}$$
  $80\% \text{ EtOH}$   $80 \text{ °C}$   $5 : 95$ 

- 21. The mechanism of the reaction leading to the major product in this case is
  - (a)  $S_N 1$  (b)  $S_N 2$  (c) E1 (d) E2
- 22. The reason there is so much substitution in this case is that
  - (a) H<sub>2</sub>O is a good nucleophile.
  - (b) EtOH is a good nucleophile.
  - (c) the reaction is reversible.
  - (d) there is no reasonably strong base present.

CI 
$$\frac{}{20\% \text{ H}_2\text{O}}$$
 + substitution  $\frac{}{65 \text{ }^{\circ}\text{C}}$   $\frac{}{36}$  :  $64$ 

- 23. The reason there is less substitution in this case than in Problem 21 is that
  - (a) alkyl chlorides react faster than alkyl bromides.
  - (b) alkyl chlorides react slower than alkyl bromides.
  - (c) tertiary alkyl halides are less likely than secondary alkyl halides to undergo substitution.
  - (d) tertiary alkyl halides do not undergo  $S_N2$  reactions.

- 24. The reason there is only one enantiomer produced in this case is that
  - (a) The nucleophile is ethoxide anion.
  - (b) The reaction mechanism involves only one intermediate.
  - (c) The reaction is stereospecific.
  - (d) The mechanism is  $S_N1$ .

$$H_2O$$
heat

OH

(17%ee)

# 25. The low EE here reflects the fact that

- (a)  $S_{\rm N}2$  reactions are not stereospecific.
- (b) The reaction goes through a cation intermediate.
- (c)  $S_N 1$  reactions lead to both substitution and elimination.
- (d) The reaction was carried out for too long, leading to the thermodynamic product.
